

29566428_FIT5149_Ass1

September 16, 2019

1 FIT5149 Assessment 1

Student Name: Jaimon Thyparambil Thomas

Student ID: 29566428

Date:15-09-2019

2 Importing necessary Libraries

```
[1]: library(psych) # for describe  
library(lattice) # for levelplot  
library(leaps) # for Regsubplots  
require(ggplot2) # for various plots
```

Loading required package: ggplot2

Registered S3 methods overwritten by 'ggplot2':

method	from
[.quosures	rlang
c.quosures	rlang
print.quosures	rlang

Attaching package: 'ggplot2'

The following objects are masked from 'package:psych':

%+%, alpha

3 Loading Data

```
[2]: data <- read.csv('train.csv', header = TRUE, sep = ',')  
unique_m <- read.csv('unique_m.csv', header = TRUE, sep = ',')
```

Analysing the general Overview of the data

```
[3]: head(data)
```

number_of_elements	mean_atomic_mass	wtd_mean_atomic_mass	gmean_atomic_mass	wtd_gmean
4	88.94447	57.86269	66.36159	36.11661
5	92.72921	58.51842	73.13279	36.39660
4	88.94447	57.88524	66.36159	36.12251
4	88.94447	57.87397	66.36159	36.11956
4	88.94447	57.84014	66.36159	36.11072
4	88.94447	57.79504	66.36159	36.09893

```
[4]: head(unique_m)
```

```
[17]: boxplot(newData, las=2, cex.axis = 1)
```

Now Lets check the correlation between all columns in the new dataset

```
[18]: #Define the color scheme
cols = colorRampPalette(c("red", "blue"))
#Plot the correlation matrix.
levelplot(cor(newData), col.regions = cols(100), main = "correlation", xlab = NULL,
          ylab = NULL,
          scales = list(x = list(rot = 90)))
```

From this plot it looks like most of the columns are highly correlated to each other. So let's try to extract the values with correlation greater than 0.8 or less than -0.8

```
[19]: used = c('critical_temp')
correlationValues = c()
correlationName = c()
correlationSign = c()
absoluteCorrelationValue = c()
for(entity in names(newData)){
  if(entity == 'critical_temp'){
    next
  }
  used = c(used,entity)
  for(var1 in names(newData)){
```

```

        if(is.element(var1, used)){
            next
        }
        if((var1!=entity) &&(cor(data[var1],data[entity])>0.8 ||
→cor(data[var1],data[entity])< -0.8 )){
            corVal <- cor(data[var1],data[entity])
            correlationValues <- c(correlationValues, corVal)
            correlationName <- c(correlationName,paste(var1,":",entity))
            if(corVal > 0){
                correlationSign <- c(correlationSign,"+ve Correlation")
            }
            else{
                correlationSign <- c(correlationSign,"-ve Correlation")
            }
            absoluteCorrelationValue <-
→c(absoluteCorrelationValue,abs(cor(data[var1],data[entity])))
        }
    }
}
temp = data.
→frame(correlationName,correlationValues,absoluteCorrelationValue,correlationSign)
newCorrelation = temp[order(-temp$absoluteCorrelationValue),]
newCorrelation

```

```
[1] "So there is about 3 entries with correlation greater than abs(0.99)"
```

3.1.2 Individual Analysis of Top 5 Correlated Variables

```
[115]: top5Columns =_
      ↪c('critical_temp','wtd_std_ThermalConductivity','range_ThermalConductivity','range_atomic_r
      ↪std_ThermalConductivity','wtd_mean_Valence')
top5ColumnsData = data[,top5Columns]
```

```
[116]: pairs(top5ColumnsData)
```

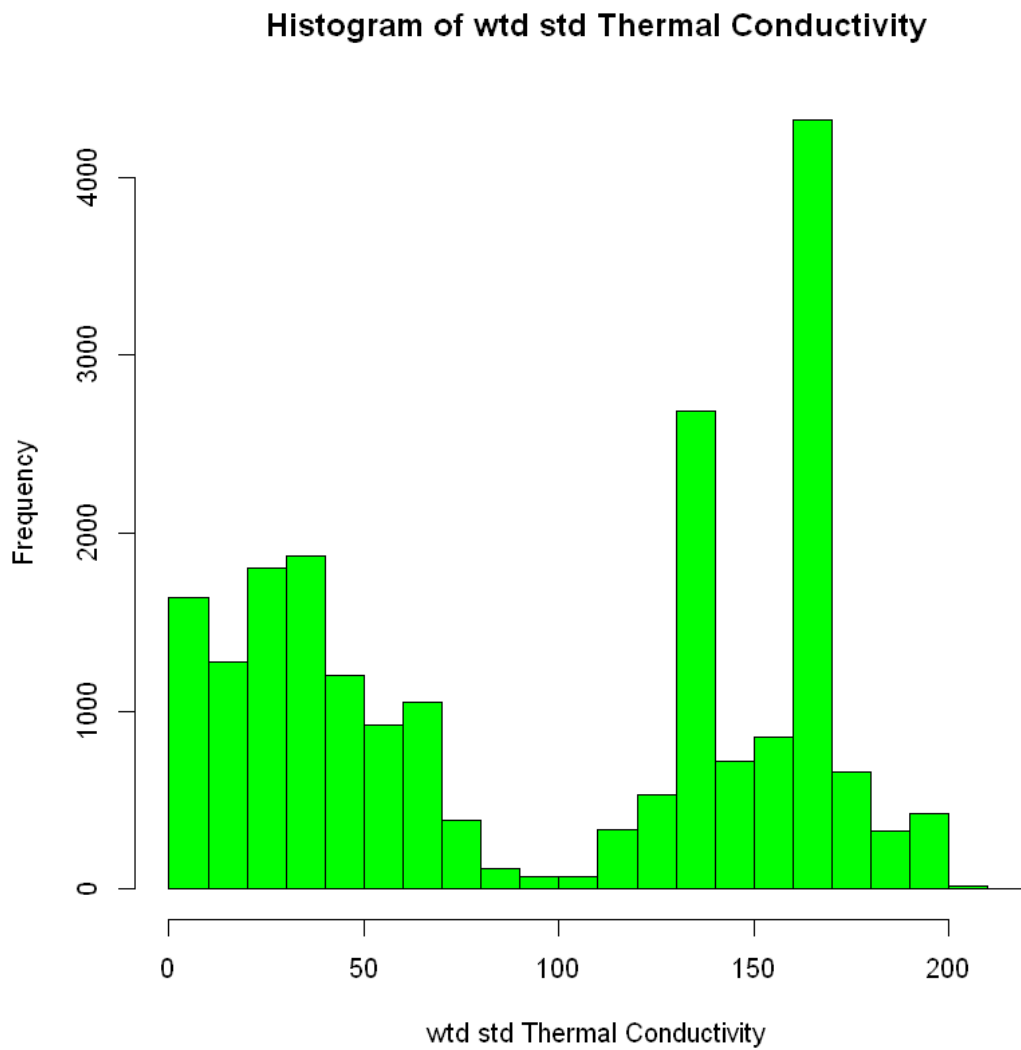

From the above plot we can see that some of the columns are linearly correlated to each other

3.1.3 Checking the internal splitup of the top 5 correlated predictors

3.1.4 wtd Std Thermal Conductivity

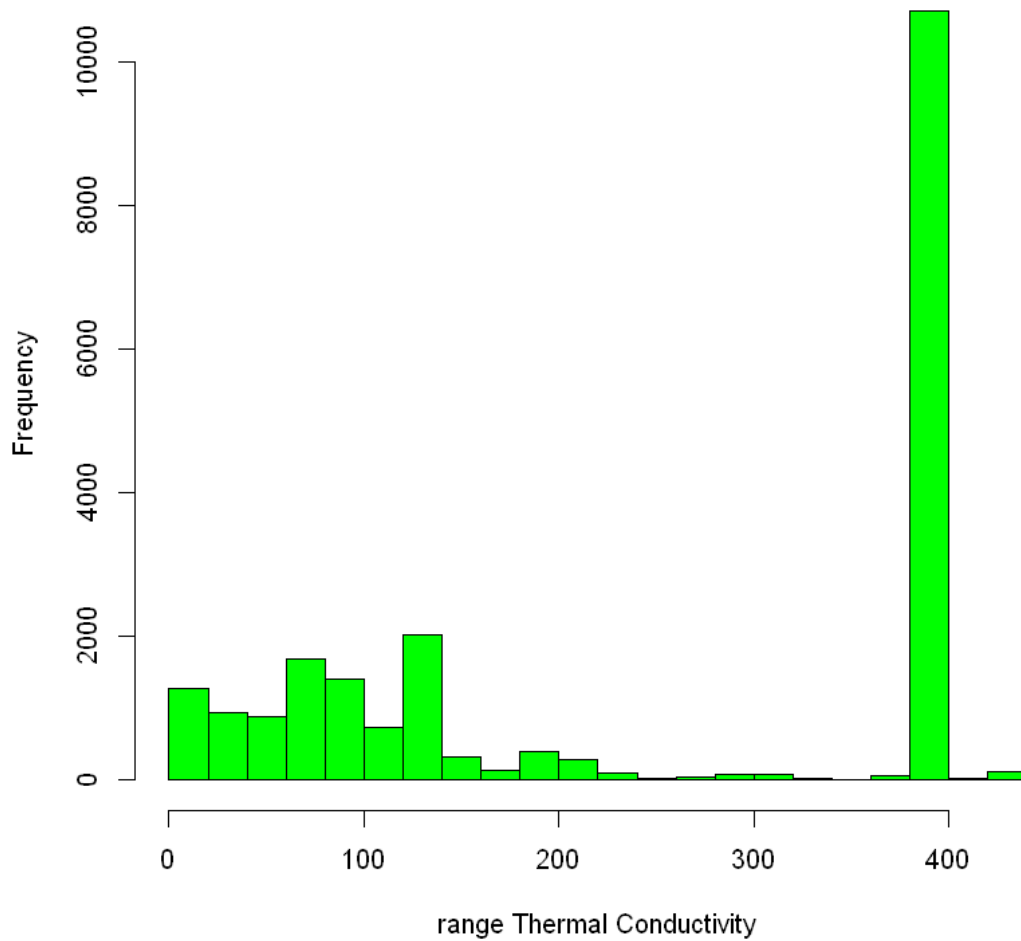

```
[23]: hist(data$wtd_std_ThermalConductivity,col="green",xlab ="wtd std Thermal_
      ↳Conductivity" ,
      main="Histogram of wtd std Thermal Conductivity")
```

3.1.5 range Thermal Conductivity

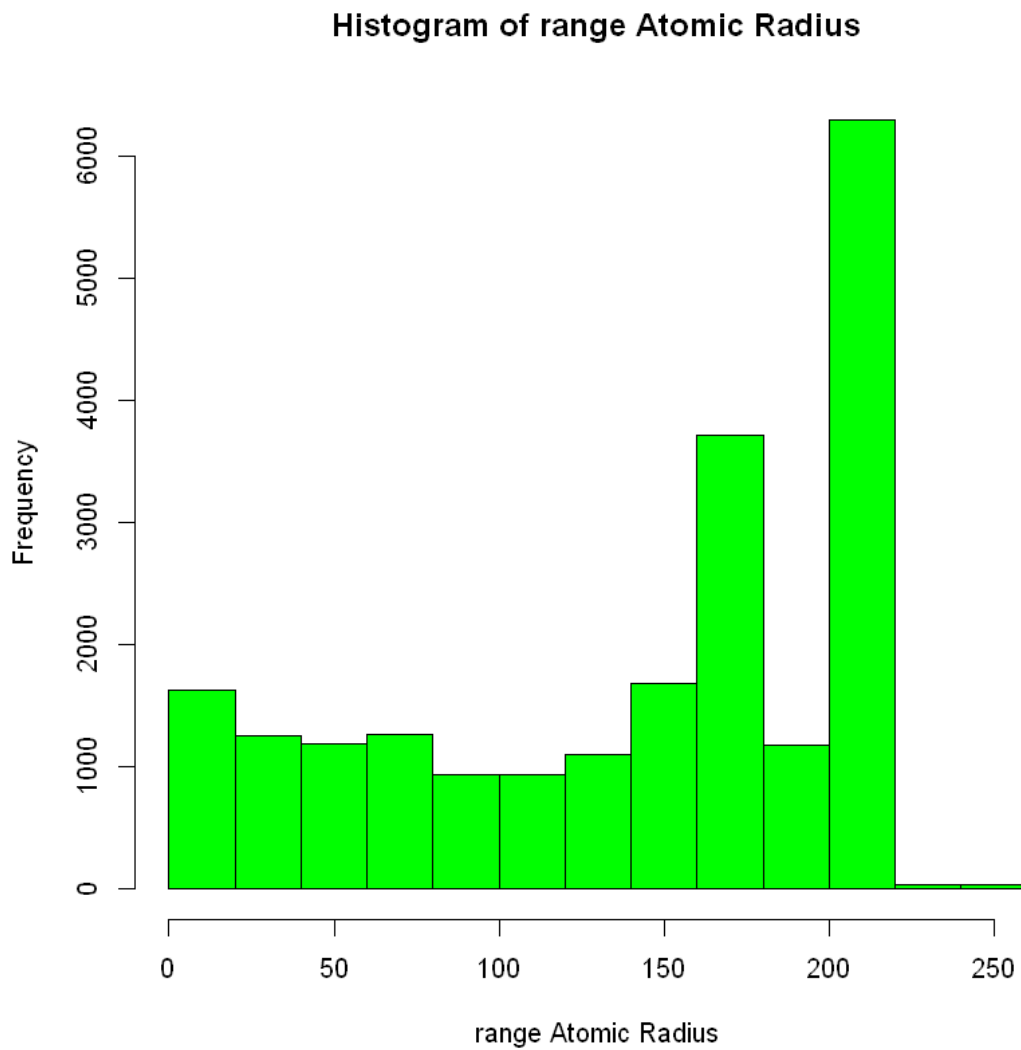

```
[24]: hist(data$range_ThermalConductivity,col="green",xlab ="range Thermal_
      ↳Conductivity" ,
      main="Histogram of range Thermal Conductivity")
```

Histogram of range Thermal Conductivity

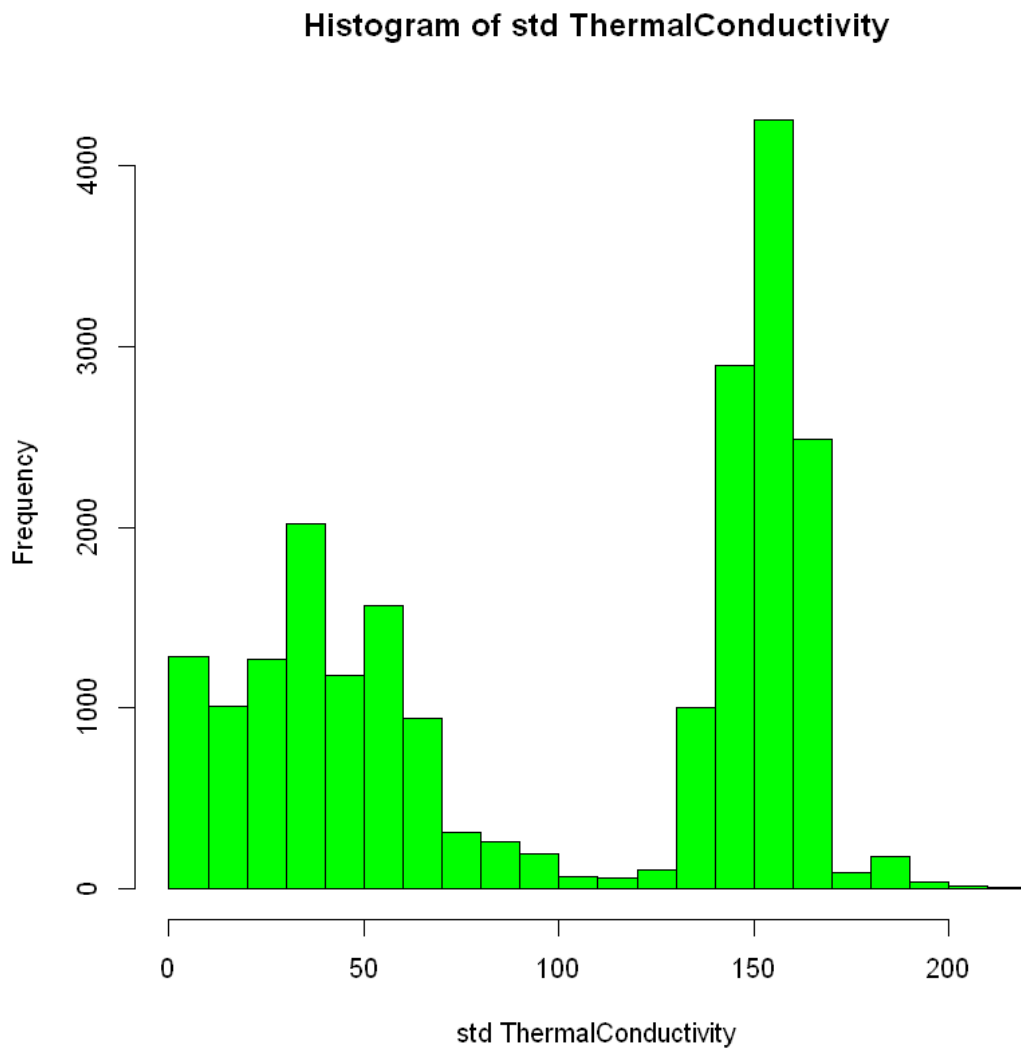

3.1.6 range atomic radius

```
[25]: hist(data$range_atomic_radius,col="green",xlab ="range Atomic Radius" ,  
          main="Histogram of range Atomic Radius")
```

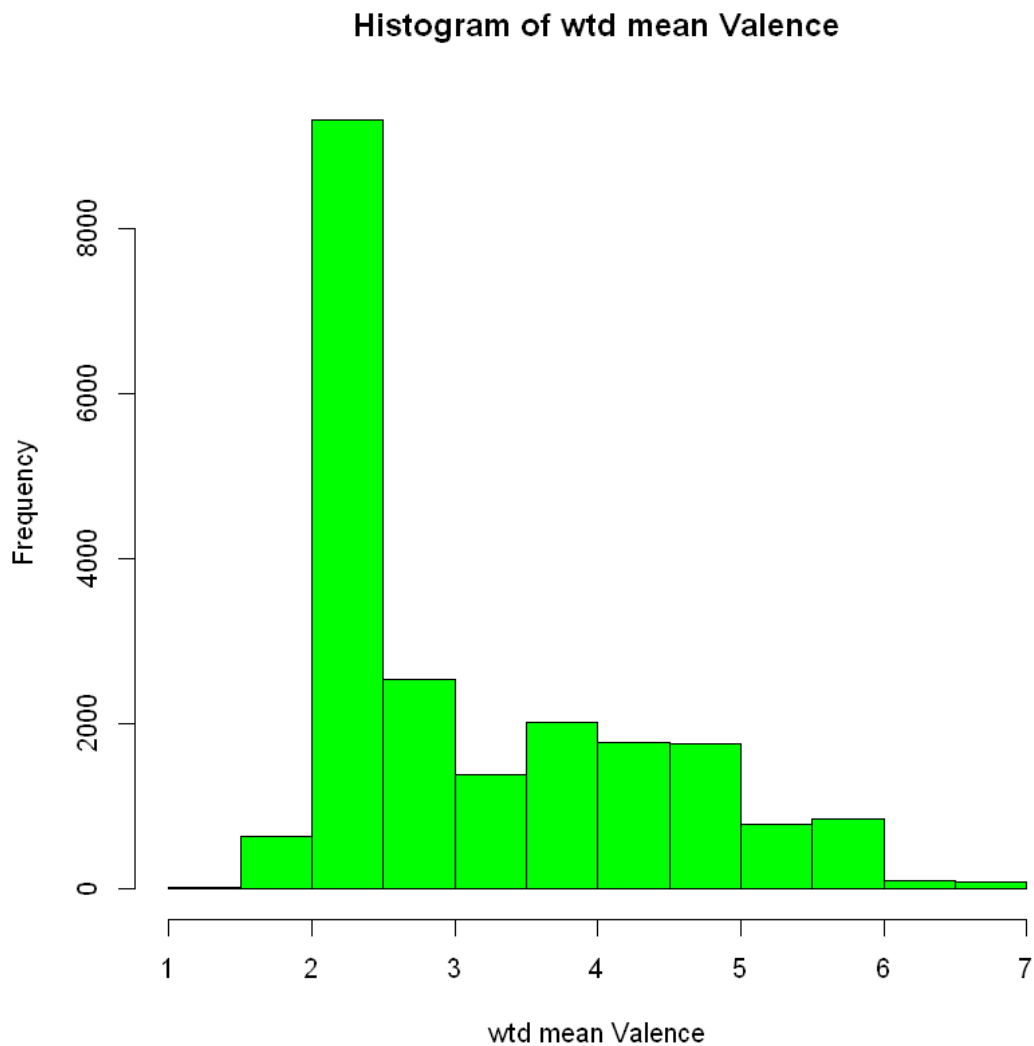

3.1.7 std_ThermalConductivity

```
[26]: hist(data$std_ThermalConductivity,col="green",xlab ="std ThermalConductivity" ,  
        main="Histogram of std ThermalConductivity")
```

3.1.8 wtd_mean_Valence

```
[27]: hist(data$wtd_mean_Valence,col="green",xlab ="wtd mean Valence" ,  
          main="Histogram of wtd mean Valence")
```

4 Models

4.1 Splitting Data into Training and Test Data

```
[28]: #Splitting the data into 70 percent training and 30 percent test data
sampleSize <- floor(0.70 * nrow(data))

## set the seed to make your partition reproducible
set.seed(123)
trainIndex <- sample(seq_len(nrow(data)), size = sampleSize)
train <- data[trainIndex, ]
test <- data[-trainIndex, ]
```

Checking train data

```
[29]: describe(train)
```

Analysis on the four plots

The **residual vs fitted plot**: This plot is used to check the linear assumption. It shows if residuals have non-linear patterns. If you find equally spread residuals around a horizontal line without distinct patterns, that is a good indication you have linear relationships. However, if the relationship between predictors and an response variable is non-linear, an obvious pattern could show up in this plot if the model cannot capture the non-linearity. The first plot above shows that there could be a non-linear relationship between critical_temp and all the predictors, as the residuals are not scattered evenly.

The **normal Q-Q plot**: The Q-Q plot (i.e., quantile-quantile plot) is a graphical tool to help us assess if a set of data plausibly came from some theoretical distribution such as a Normal. For example, if we run a statistical analysis that assumes our dependent variable is Normally distributed, we can use a Normal Q-Q plot to check that assumption. In the case of linear regression analysis, we assume that residual is normally distributed with constant variance and mean equal to zero. The normal Q-Q plot shows if residuals are normally distributed. Generally It is good if

residuals are lined well on the straight dashed line. In the above Plot it seems that the residuals are approximately distributed normally

The **scale-location plot**: It is used to check the assumption of equal variance by showing if residuals are spread equally along the ranges of predictors. It is good if we can see a horizontal line with equally (randomly) spread points. The scale-location plot shows that the residuals appear randomly spread.

The **residual-leverage plot**: it helps us identify influential data samples. Not all outliers are influential in linear regression analysis. Here we care about the samples that are influential to determine the regression line. These samples can very influential even if they look to be within a reasonable range of the values. They can alter the results if we exclude them from analysis. In the residual-leverage plot, we look for outlying values at the upper right corner or at the lower right corner. Samples located in those places can be influential against a regression line. We usually use Cook's distance, indicated by a red dash line. When samples are outside of the Cook's distance (i.e, they have high Cook's distance scores, Cook's distance measures how much the entire regression function changes when the i-th case is deleted.), the samples are influential to the regression results. The regression results will be altered if we exclude those samples. Here in this plot we can barely see Cook's distance lines because all cases are well inside of the Cook's distance lines. Therefore no influential cases are observed.

4.1.2 Linear Fit just based on the columns Which have higher correlation that is greater than 0.5 or less than -0.5

```

```
[1] "All Predictors - Adjusted R-Square: 0.7355"
```

```
[1] "Highly Correlated Data - Adjusted R-Square: 0.6461"
```

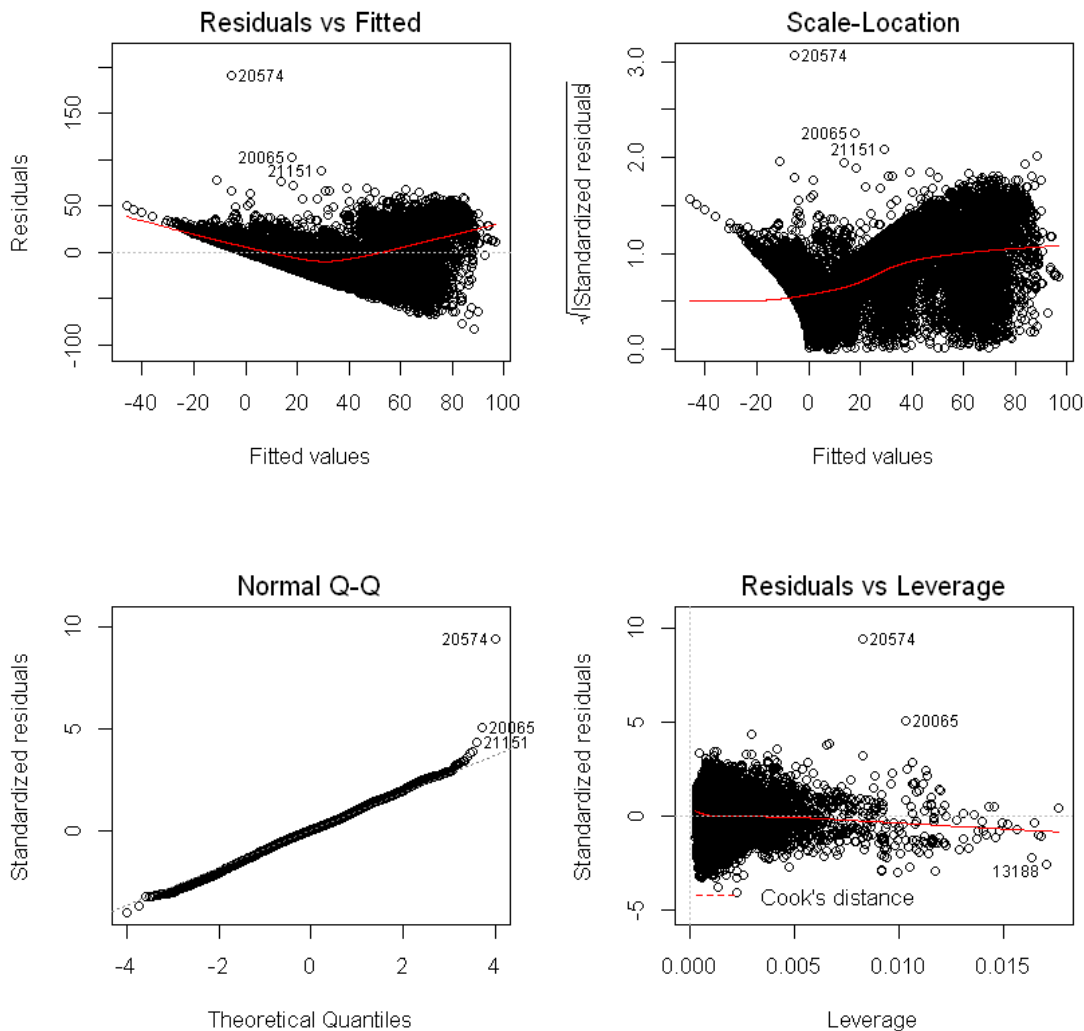

Here we can see that the Adjusted R square has been reduced significantly Which indicates the new model might not be a good model

```
[38]: # -1 to remove the row with value as intercept
print(paste("we can see that in this model around", nrow(fit.correlated.
  ↳summary$coefficients)-1,"predictors is been used"))
```

```
[1] "we can see that in this model around 25 predictors is been used"
```

Lets Check the various Residuals plot

```
[39]: par(mfcol=c(2,2))
plot(fit.correlated)
```

Analysis on the four plots

The **residual vs fitted plot**: This plot is used to check the linear assumption. It shows if residuals have non-linear patterns. If you find equally spread residuals around a horizontal line without distinct patterns, that is a good indication you have linear relationships. However, if the relationship between predictors and an response variable is non-linear, an obvious pattern could show up in this plot if the model cannot capture the non-linearity. The first plot above shows that there could be a non-linear relationship between critical_temp and all the predictors, as the residuals are not scattered evenly.

The **normal Q-Q plot**: The Q-Q plot (i.e., quantile-quantile plot) is a graphical tool to help us assess if a set of data plausibly came from some theoretical distribution such as a Normal. For example, if we run a statistical analysis that assumes our dependent variable is Normally distributed, we can use a Normal Q-Q plot to check that assumption. In the case of linear regression analysis, we assume that residual is normally distributed with constant variance and mean equal to zero. The normal Q-Q plot shows if residuals are normally distributed. Generally It is good if

residuals are lined well on the straight dashed line. In the above Plot it seems that the residuals are approximately distributed normally

The **scale-location plot**: It is used to check the assumption of equal variance by showing if residuals are spread equally along the ranges of predictors. It is good if we can see a horizontal line with equally (randomly) spread points. The scale-location plot shows that the residuals appear randomly spread.

The **residual-leverage plot**: it helps us identify influential data samples. Not all outliers are influential in linear regression analysis. Here we care about the samples that are influential to determine the regression line. These samples can be very influential even if they look to be within a reasonable range of the values. They can alter the results if we exclude them from analysis. In the residual-leverage plot, we look for outlying values at the upper right corner or at the lower right corner. Samples located in those places can be influential against a regression line. We usually use Cook's distance, indicated by a red dash line. When samples are outside of the Cook's distance (i.e., they have high Cook's distance scores, Cook's distance measures how much the entire regression function changes when the i-th case is deleted.), the samples are influential to the regression results. The regression results will be altered if we exclude those samples. Here in this plot we can barely see Cook's distance lines because all cases are well inside of the Cook's distance lines. Therefore no influential cases are observed.

4.1.3 Perform F-tests by comparing the two models using the anova() function

```
[40]: anova(fit.all, fit.correlated)
```

Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
14802	4594899	NA	NA	NA	NA
14858	6170995	-56	-1576097	90.66492	0

Here with respect to the original Fit (including all predictors) we can see that in the new model the predictors are more correlated as p value is 0. we can also see that in the new fit there is predictors less compared to the original which makes it less complex. But we also see that RSS value has been increased significantly which is very bad.

Trying to Add the top 3 inter correlated columns that we found earlier and checking its adjusted rsquare val

```
[117]: summary(update(fit.correlated, . ~ . + entropy_fie:entropy_atomic_radius +  
->wtd_mean_Valence:wtd_gmean_Valence + entropy_Valence:entropy_fie))
```

Call:

```

entropy_fie:entropy_Valence	-1.586e+02	1.226e+01	-12.931	< 2e-16	***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 20.15 on 14855 degrees of freedom

Multiple R-squared: 0.6548, Adjusted R-squared: 0.6541

F-statistic: 1006 on 28 and 14855 DF, p-value: < 2.2e-16

Still the adjusted R square val is significantly low compared to all predictors list. So we can ignore this model

4.1.4 Linear Fit by taking only the relevant columns based on the no of stars that is based on the p value

```
[41]: fit.starred = lm(critical_temp~.-wtd_entropy_atomic_mass
                        -wtd_range_atomic_mass
                        -wtd_std_atomic_mass
                        -wtd_std_fie
                        -gmean_atomic_radius
                        -wtd_mean_Density
                        -wtd_range_Density
                        -mean_ElectronAffinity
                        -entropy_ElectronAffinity
                        -std_FusionHeat
                        -mean_ThermalConductivity
                        -wtd_entropy_ThermalConductivity
                        -wtd_std_ThermalConductivity
                        -wtd_range_Valence, data = train)
fit.starred.summary = summary(fit.starred)
```

```
[42]: # -1 to remove the row with value as intercept
print(paste("we can see that in this model around", nrow(fit.starred.
  ↳summary$coefficients)-1,"predictors is been used"))
```

```
[1] "we can see that in this model around 67 predictors is been used"
```

```
[43]: print(paste("All Predictors - Adjusted R-Square:",round(fit.all.summary$adj.r.
  ↳squared,4)))
print(paste("Starred Data - Adjusted R-Square:",round(fit.starred.summary$adj.r.
  ↳squared,4)))
```

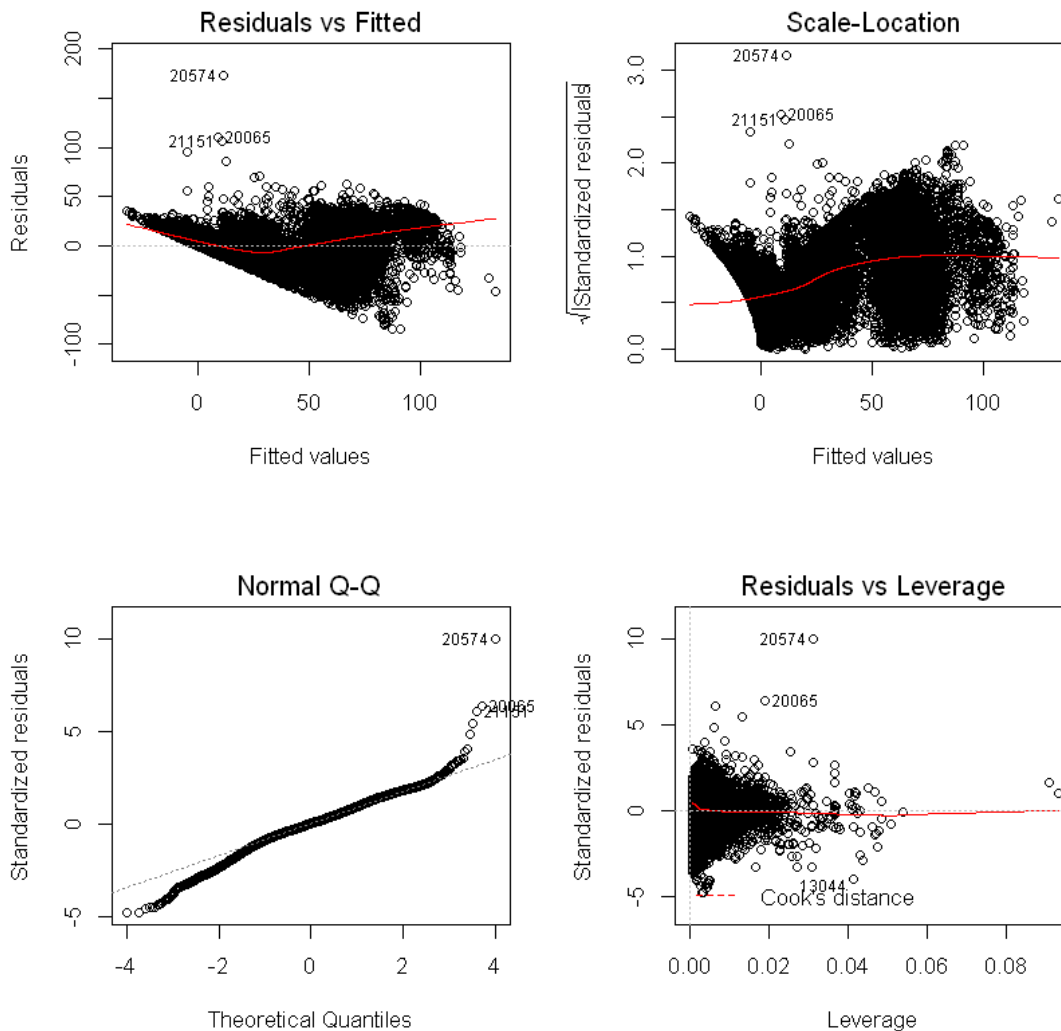

```
[1] "All Predictors - Adjusted R-Square: 0.7355"
```

```
[1] "Starred Data - Adjusted R-Square: 0.7353"
```

Here we can see that the adjusted R-square is decreased but only for a small amount which indicates that it might be a better model compared to original model(including all predicates) as this model is comparatively less complex

Lets Check the various Residuals plot

```
[44]: par(mfcol=c(2,2))
plot(fit.starred)
```

Analysis on the four plots

The **residual vs fitted plot**: This plot is used to check the linear assumption. It shows if residuals have non-linear patterns. If you find equally spread residuals around a horizontal line without distinct patterns, that is a good indication you have linear relationships. However, if the relationship between predictors and an response variable is non-linear, an obvious pattern could show up in this plot if the model cannot capture the non-linearity. The first plot above shows that there could be a non-linear relationship between critical_temp and all the predictors, as the residuals are not scattered evenly.

The **normal Q-Q plot**: The Q-Q plot (i.e., quantile-quantile plot) is a graphical tool to help us assess if a set of data plausibly came from some theoretical distribution such as a Normal. For example, if we run a statistical analysis that assumes our dependent variable is Normally distributed, we can use a Normal Q-Q plot to check that assumption. In the case of linear regression analysis, we assume that residual is normally distributed with constant variance and mean equal to zero. The normal Q-Q plot shows if residuals are normally distributed. Generally It is good if

residuals are lined well on the straight dashed line. In the above Plot it seems that the residuals are approximately distributed normally

The **scale-location plot**: It is used to check the assumption of equal variance by showing if residuals are spread equally along the ranges of predictors. It is good if we can see a horizontal line with equally (randomly) spread points. The scale-location plot shows that the residuals appear randomly spread.

The **residual-leverage plot**: it helps us identify influential data samples. Not all outliers are influential in linear regression analysis. Here we care about the samples that are influential to determine the regression line. These samples can be very influential even if they look to be within a reasonable range of the values. They can alter the results if we exclude them from analysis. In the residual-leverage plot, we look for outlying values at the upper right corner or at the lower right corner. Samples located in those places can be influential against a regression line. We usually use Cook's distance, indicated by a red dash line. When samples are outside of the Cook's distance (i.e, they have high Cook's distance scores, Cook's distance measures how much the entire regression function changes when the i-th case is deleted.), the samples are influential to the regression results. The regression results will be altered if we exclude those samples. Here in this plot we can barely see Cook's distance lines because all cases are well inside of the Cook's distance lines. Therefore no influential cases are observed.

4.1.5 Perform F-tests by comparing the two models using the anova() function

```
[45]: anova(fit.all, fit.starred)
```

Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
14802	4594899	NA	NA	NA	NA
14816	4602237	-14	-7338.493	1.688587	0.0507471

Here with respect to the original Fit (including all predictors) we can see that in the new model the predictors are more correlated as p value is approx 0.05. we can also see that in the new fit the no of predictors is less compared to the original which makes it less complex. Also we can see that there is only slight increase in RSS compared to the original fit. So due to all these factors the new model looks better than the all predictors model

4.1.6 Generating a linear Fit using forward step function

```
[46]: fit.step.forward = step(lm(critical_temp~1 , data = train),direction = "forward",scope=formula(lm(critical_temp~.,train)))
fit.step.forward.summary <-summary(fit.step.forward)
fit.step.forward.summary
```

Start: AIC=105198.7

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 17.62 on 14806 degrees of freedom

Multiple R-squared: 0.7368, Adjusted R-squared: 0.7354

F-statistic: 538.2 on 77 and 14806 DF, p-value: < 2.2e-16

```
[47]: # -1 to remove the row with value as intercept
print(paste("we can see that in this model around", nrow(fit.step.forward.
  ↳summary$coefficients)-1,"predictors is been used"))
```

```
[1] "we can see that in this model around 77 predictors is been used"
```

```
[48]: print(paste("All Predictors - Adjusted R-Square:",round(fit.all.summary$adj.r.
  ↳squared,4)))
print(paste("Step Forward Data - Adjusted R-Square:",round(fit.step.forward.
  ↳summary$adj.r.squared,4)))
```

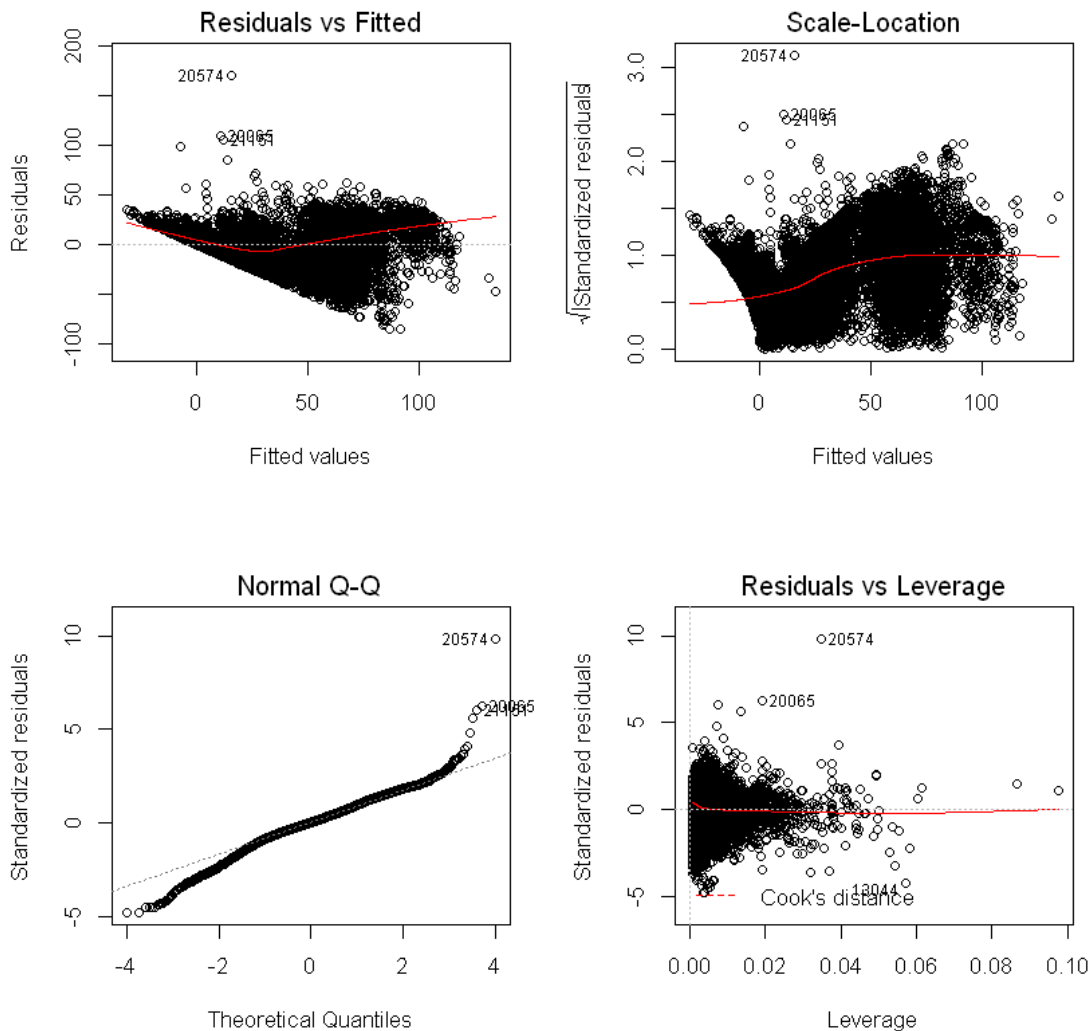

```
[1] "All Predictors - Adjusted R-Square: 0.7355"
```

```
[1] "Step Forward Data - Adjusted R-Square: 0.7354"
```

Here we can see that the adjusted R-square is decreased but only for a small amount which indicates that it might be a better model compared to original model(including all predicates) as this model is comparatively less complex

Lets Check the various Residuals plot

```
[49]: par(mfcol=c(2,2))
plot(fit.step.forward)
```

Analysis on the four plots

The **residual vs fitted plot**: This plot is used to check the linear assumption. It shows if residuals have non-linear patterns. If you find equally spread residuals around a horizontal line without distinct patterns, that is a good indication you have linear relationships. However, if the relationship between predictors and an response variable is non-linear, an obvious pattern could show up in this plot if the model cannot capture the non-linearity. The first plot above shows that there could be a non-linear relationship between critical_temp and all the predictors, as the residuals are not scattered evenly.

The **normal Q-Q plot**: The Q-Q plot (i.e., quantile-quantile plot) is a graphical tool to help us assess if a set of data plausibly came from some theoretical distribution such as a Normal. For example, if we run a statistical analysis that assumes our dependent variable is Normally distributed, we can use a Normal Q-Q plot to check that assumption. In the case of linear regression analysis, we assume that residual is normally distributed with constant variance and mean equal to zero. The normal Q-Q plot shows if residuals are normally distributed. Generally It is good if

residuals are lined well on the straight dashed line. In the above Plot it seems that the residuals are approximately distributed normally

The **scale-location plot**: It is used to check the assumption of equal variance by showing if residuals are spread equally along the ranges of predictors. It is good if we can see a horizontal line with equally (randomly) spread points. The scale-location plot shows that the residuals appear randomly spread.

The **residual-leverage plot**: it helps us identify influential data samples. Not all outliers are influential in linear regression analysis. Here we care about the samples that are influential to determine the regression line. These samples can be very influential even if they look to be within a reasonable range of the values. They can alter the results if we exclude them from analysis. In the residual-leverage plot, we look for outlying values at the upper right corner or at the lower right corner. Samples located in those places can be influential against a regression line. We usually use Cook's distance, indicated by a red dash line. When samples are outside of the Cook's distance (i.e, they have high Cook's distance scores, Cook's distance measures how much the entire regression function changes when the i-th case is deleted.), the samples are influential to the regression results. The regression results will be altered if we exclude those samples. Here in this plot we can barely see Cook's distance lines because all cases are well inside of the Cook's distance lines. Therefore no influential cases are observed.

4.1.7 Perform F-tests by comparing the two models using the anova() function

```
[50]: anova(fit.all, fit.step.forward)
```

Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
14802	4594899	NA	NA	NA	NA
14806	4597847	-4	-2948.009	2.374178	0.04986433

Here with respect to the original Fit (including all predictors) we can see that in the new model the predictors are more correlated as p value is less than 0.05. we can also see that in the new fit the no of predictors is less compared to the original which makes it less complex. Also we can see that there is only slight increase in RSS compared to the original fit. So due to all these factors the new model looks better than the all predictors model

4.1.8 Generating a linear Fit using backward step function

```
[51]: fit.step.backward = step(lm(critical_temp~. , data = train),direction = "backward")
fit.step.backward.summary <-summary(fit.step.backward)
fit.step.backward.summary
```

Start: AIC=85485.27

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 17.62 on 14813 degrees of freedom

Multiple R-squared: 0.7367, Adjusted R-squared: 0.7355

F-statistic: 592.2 on 70 and 14813 DF, p-value: < 2.2e-16

```
[52]: # -1 to remove the row with value as intercept
print(paste("we can see that in this model around", nrow(fit.step.backward.
  ↳summary$coefficients)-1,"predictors is been used"))
```

```
[1] "we can see that in this model around 70 predictors is been used"
```

```
[53]: print(paste("All Predictors - Adjusted R-Square:",round(fit.all.summary$adj.r.
  ↳squared,4)))
```

```
print(paste("Step Backward Data - Adjusted R-Square:",round(fit.step.backward.
→summary$adj.r.squared,4)))
```

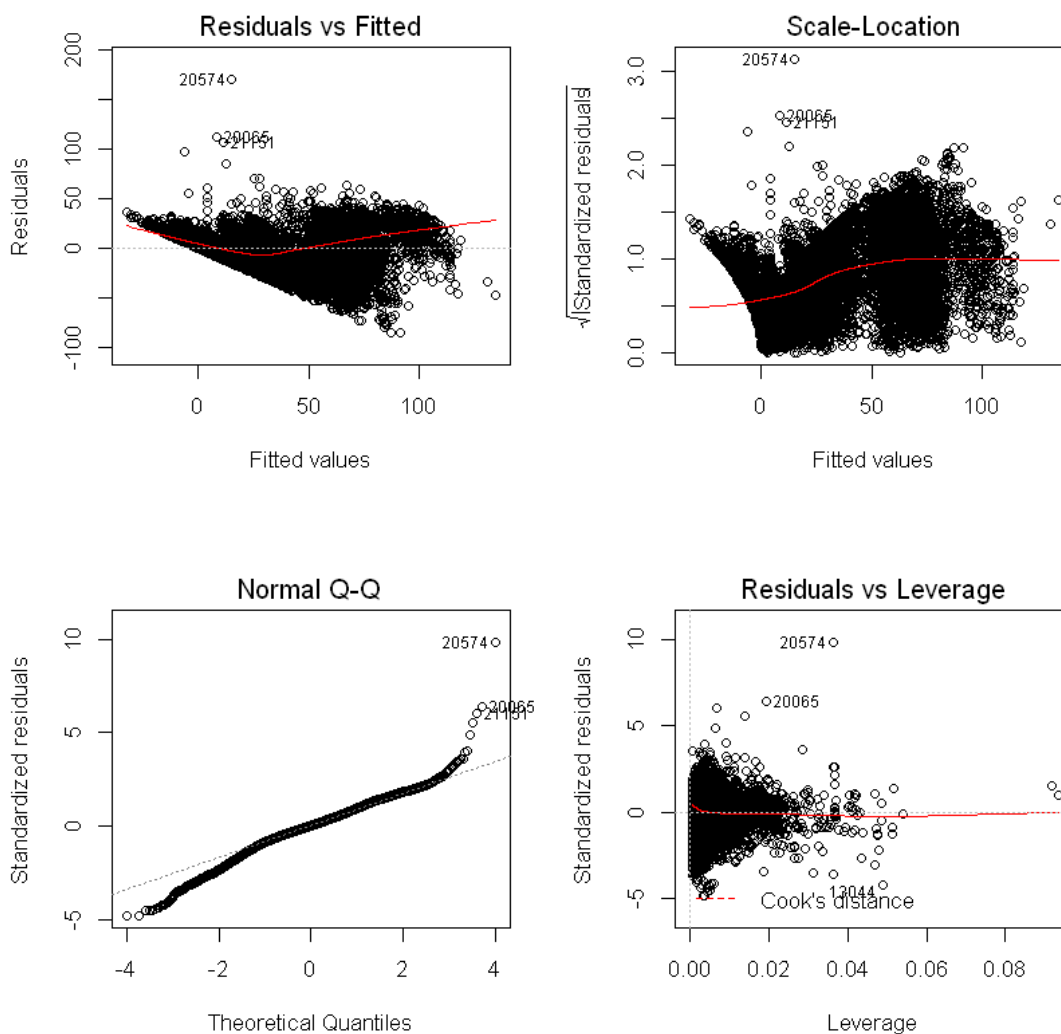

```
[1] "All Predictors - Adjusted R-Square: 0.7355"
```

```
[1] "Step Backward Data - Adjusted R-Square: 0.7355"
```

Here we can see that the adjusted R-square is almost equal which indicates that it might be a better model compared to original model(including all predicates) as this model is comparatively less complex

Lets Check the various Residuals plot

```
[54]: par(mfcol=c(2,2))
plot(fit.step.backward)
```

Analysis on the four plots

The **residual vs fitted plot**: This plot is used to check the linear assumption. It shows if residuals have non-linear patterns. If you find equally spread residuals around a horizontal line without distinct patterns, that is a good indication you have linear relationships. However, if the relationship between predictors and an response variable is non-linear, an obvious pattern could show up in this plot if the model cannot capture the non-linearity. The first plot above shows that there could be a non-linear relationship between critical_temp and all the predictors, as the residuals are not scattered evenly.

The normal **Q-Q plot**: The Q-Q plot (i.e., quantile-quantile plot) is a graphical tool to help us assess if a set of data plausibly came from some theoretical distribution such as a Normal. For example, if we run a statistical analysis that assumes our dependent variable is Normally distributed, we can use a Normal Q-Q plot to check that assumption. In the case of linear regression analysis, we assume that residual is normally distributed with constant variance and mean equal to zero. The normal Q-Q plot shows if residuals are normally distributed. Generally It is good if residuals are lined well on the straight dashed line. In the above Plot it seems that the residuals are approximatly distributed normally

The **scale-location plot**: It is used to check the assumption of equal variance by showing if residuals are spread equally along the ranges of predictors. It is good if we can see a horizontal line with equally (randomly) spread points. The scale-location plot shows that the residuals appear randomly spread.

The **residual-leverage plot**: it helps us identify influential data samples. Not all outliers are influential in linear regression analysis. Here we care about the samples that are influential to determine the regression line. These samples can very influential even if they look to be within a reasonable range of the values. They can alter the results if we exclude them from analysis. In the residual-leverage plot, we look for outlying values at the upper right corner or at the lower right corner. Samples located in those places can be influential against a regression line. We usually use Cook's distance, indicated by a red dash line. When samples are outside of the Cook's distance (i.e, they have high Cook's distance scores, Cook's distance measures how much the entire regression function changes when the i-th case is deleted.), the samples are influential to the regression results. The regression results will be altered if we exclude those samples. Here in this plot we can barely see Cook's distance lines because all cases are well inside of the Cook's distance lines. Therefore no influential cases are observed.

4.1.9 Perform F-tests by comparing the two models using the anova() function

```
[55]: anova(fit.all, fit.step.backward)
```

Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
14802	4594899	NA	NA	NA	NA
14813	4598388	-11	-3488.991	1.021766	0.4234977

Here with respect to the original Fit (including all predicators) we can see that in the new model the predictors are not much correlated as p value is greater than 0.05. we can also see that in the new fit the no of predictors is less compared to the original which makes it less complex. Also we can see that there is only slight increase in RSS compared to the original fit. So due to all these factors the new model looks better than the all predictors model

We Know that step is done by finding least AIC value. But a better model can also be found using other factors similar to AIC like BIC etc

4.1.10 Performing best subset selection

4.1.11 Using forward Selection

```
[56]: fit.reg.forward <- regsubsets(critical_temp ~ ., data = train, nvmax = 81,
  ↪method = "forward")
fit.reg.forward.summary <- summary(fit.reg.forward)
fit.reg.forward.summary
```

Subset selection object

Call: regsubsets.formula(critical_temp ~ ., data = train, nvmax = 81,
method = "forward")

81 Variables (and intercept)

      side = 3, line = -2, outer = TRUE)

```

Plots of C_p , BIC, adjusted R^2 and RSS for forward stepwise selection

BIC (or Bayesian information criteria) is a variant of AIC with a stronger penalty for including additional variables to the model. We know that lesser the value of BIC better the model

```
[58]: print(paste("we can see that min value of BIC was found in a model with", which.
  ↳ min(fit.reg.forward.summary$bic), "predictors"))
```

```
[1] "we can see that min value of BIC was found in a model with 73 predictors"
```

We also know that bigger the value of adjusted R square better the model

```
[59]: print(paste("we can see that max value of Adjusted R Square was found in a_
  ↳ model with",
    which.max(fit.reg.forward.summary$adjr2), "predictors"))
```

```
[1] "we can see that max value of Adjusted R Square was found in a model with 81
predictors"
```

Mallows Cp: A variant of AIC developed by Colin Mallows. We also Know that the smaller the value of Cp better the model

```
[60]: print(paste("we can see that max value of Cp was found in a model with", which.
  →min(fit.reg.forward.summary$cp), "predictors"))
```

```
[1] "we can see that max value of Cp was found in a model with 81 predictors"
```

Here we can see that based on both Cp and Adjusted R2 the best model should have 81 predicates. Which is same as the all predictors model

So lets analyse the case with lowest BIC that is the model with 73 predictors

```

wtd_std_Valence	-2.036e+01	1.059e+00	-19.221	< 2e-16	***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 17.63 on 14810 degrees of freedom

Multiple R-squared: 0.7365, Adjusted R-squared: 0.7352

F-statistic: 567.2 on 73 and 14810 DF, p-value: < 2.2e-16

```
[64]: # -1 to remove the row with value as intercept
print(paste("we can see that in this model around", nrow(fit.reg.f.bic.
  ↳summary$coefficients)-1,"predictors is been used"))
```

```
[1] "we can see that in this model around 73 predictors is been used"
```

```
[65]: print(paste("All Predictors - Adjusted R-Square:",round(fit.reg.f.bic.
  ↳summary$adj.r.squared,4)))
print(paste("Based on Min BIC Val - Adjusted R-Square:",round(fit.reg.f.bic.
  ↳summary$adj.r.squared,4)))
```

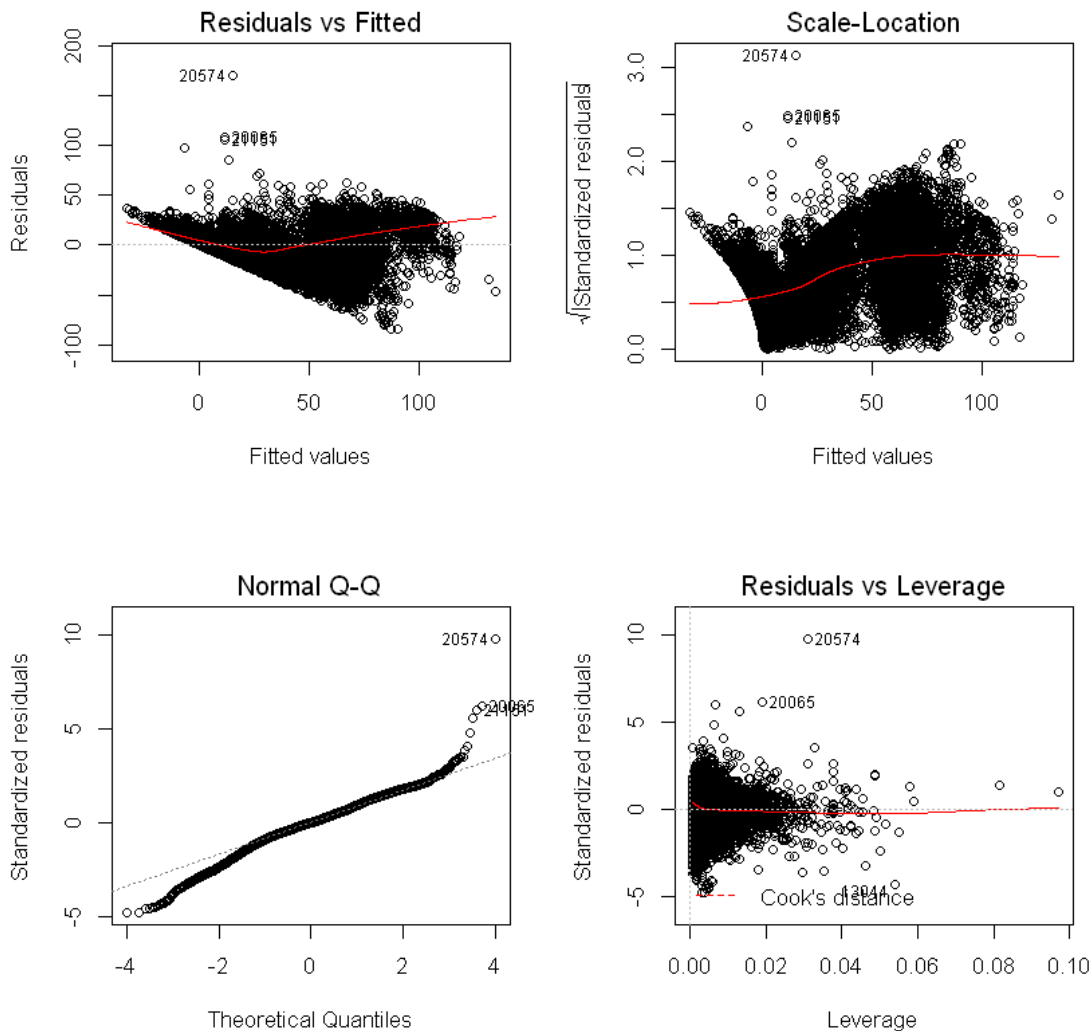

```
[1] "All Predictors - Adjusted R-Square: 0.7352"
```

```
[1] "Based on Min BIC Val - Adjusted R-Square: 0.7352"
```

Here we can see that the adjusted R-square is decreased but only for a small amount which indicates that it might be a better model compared to original model(including all predicates) as this model is comparatively less complex

Lets Check the various Residuals plot

```
[66]: par(mfcol=c(2,2))
plot(fit.reg.f.bic)
```

Analysis on the four plots

The **residual vs fitted plot**: This plot is used to check the linear assumption. It shows if residuals have non-linear patterns. If you find equally spread residuals around a horizontal line without distinct patterns, that is a good indication you have linear relationships. However, if the relationship between predictors and an response variable is non-linear, an obvious pattern could show up in this plot if the model cannot capture the non-linearity. The first plot above shows that there could be a non-linear relationship between critical_temp and all the predictors, as the residuals are not scattered evenly.

The **normal Q-Q plot**: The Q-Q plot (i.e., quantile-quantile plot) is a graphical tool to help us assess if a set of data plausibly came from some theoretical distribution such as a Normal. For example, if we run a statistical analysis that assumes our dependent variable is Normally distributed, we can use a Normal Q-Q plot to check that assumption. In the case of linear regression analysis, we assume that residual is normally distributed with constant variance and mean equal to zero. The normal Q-Q plot shows if residuals are normally distributed. Generally It is good if

residuals are lined well on the straight dashed line. In the above Plot it seems that the residuals are approximately distributed normally

The **scale-location plot**: It is used to check the assumption of equal variance by showing if residuals are spread equally along the ranges of predictors. It is good if we can see a horizontal line with equally (randomly) spread points. The scale-location plot shows that the residuals appear randomly spread.

The **residual-leverage plot**: it helps us identify influential data samples. Not all outliers are influential in linear regression analysis. Here we care about the samples that are influential to determine the regression line. These samples can be very influential even if they look to be within a reasonable range of the values. They can alter the results if we exclude them from analysis. In the residual-leverage plot, we look for outlying values at the upper right corner or at the lower right corner. Samples located in those places can be influential against a regression line. We usually use Cook's distance, indicated by a red dash line. When samples are outside of the Cook's distance (i.e., they have high Cook's distance scores, Cook's distance measures how much the entire regression function changes when the i-th case is deleted.), the samples are influential to the regression results. The regression results will be altered if we exclude those samples. Here in this plot we can barely see Cook's distance lines because all cases are well inside of the Cook's distance lines. Therefore no influential cases are observed.

4.1.12 Perform F-tests by comparing the two models using the `anova()` function

```
[67]: anova(fit.all, fit.reg.f.bic)
```

Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
14802	4594899	NA	NA	NA	NA
14810	4601730	-8	-6831.795	2.750992	0.004923194

Here with respect to the original Fit (including all predictors) we can see that in the new model the predictors are more correlated as p value is less than 0.05. we can also see that in the new fit the no of predictors is less compared to the original which makes it less complex. Also we can see that there is only slight increase in RSS compared to the original fit. So due to all these factors the new model looks better than the all predictors model

4.1.13 Using Backward Selection

```
[68]: fit.reg.backward <- regsubsets(critical_temp ~ ., data = train, nvmax = 81,
  ↪method = "backward")
fit.reg.backward.summary <- summary(fit.reg.backward)
fit.reg.backward.summary
```

Subset selection object

Call: `regsubsets.formula(critical_temp ~ ., data = train, nvmax = 81, method = "backward")`

```

Plots of C_p, BIC, adjusted R² and RSS for backward stepwise selection

BIC (or Bayesian information criteria) is a variant of AIC with a stronger penalty for including additional variables to the model. We know that lesser the value of BIC better the model

```
[70]: print(paste("we can see that min value of BIC was found in a model with", which.
      ↪min(fit.reg.backward.summary$bic), "predictors"))
```

```
[1] "we can see that min value of BIC was found in a model with 60 predictors"
```

We also know that bigger the value of adjusted R square better the model

```
[71]: print(paste("we can see that max value of Adjusted R Square was found in a
      ↪model with",
      which.max(fit.reg.backward.summary$adjr2), "predictors"))
```

```
[1] "we can see that max value of Adjusted R Square was found in a model with 76
predictors"
```

Mallows Cp: A variant of AIC developed by Colin Mallows. We also Know that the smaller the value of Cp better the model

```
[72]: print(paste("we can see that max value of Cp was found in a model with", which.
      ↪min(fit.reg.backward.summary$cp), "predictors"))
```

```
[1] "we can see that max value of Cp was found in a model with 70 predictors"
```

Here we can see that all of them have different no of predictors. So lets start from analysing the best model based on BIC ie 60 predictors

based on BIC

```

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 17.64 on 14823 degrees of freedom

Multiple R-squared: 0.7358, Adjusted R-squared: 0.7347

F-statistic: 688 on 60 and 14823 DF, p-value: < 2.2e-16

```
[76]: # -1 to remove the row with value as intercept
print(paste("we can see that in this model around", nrow(fit.reg.b.bic.
  ↳summary$coefficients)-1,"predictors is been used"))
```

```
[1] "we can see that in this model around 60 predictors is been used"
```

```
[77]: print(paste("All Predictors - Adjusted R-Square:",round(fit.all.summary$adj.r.
  ↳squared,4)))
print(paste("Based on Min BIC Val - Adjusted R-Square:",round(fit.reg.b.bic.
  ↳summary$adj.r.squared,4)))
```

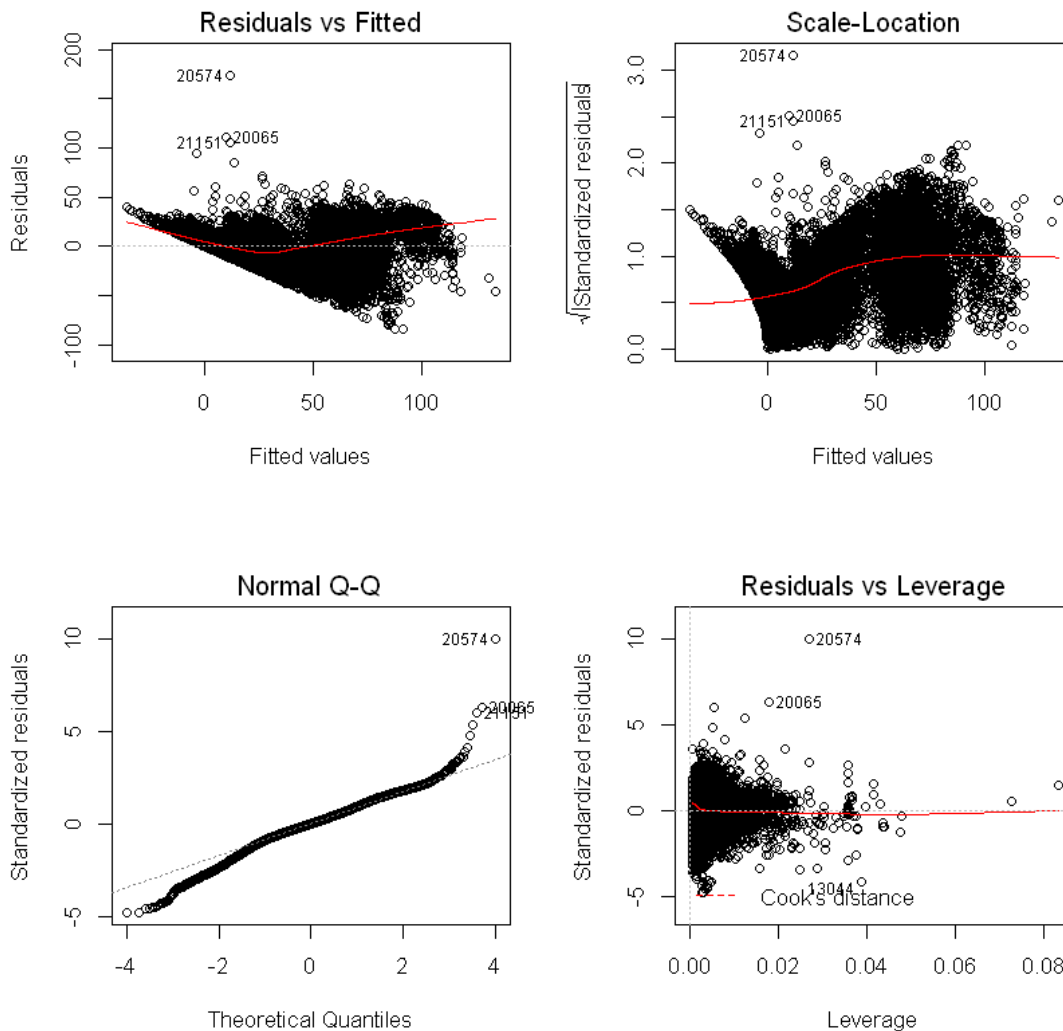

```
[1] "All Predictors - Adjusted R-Square: 0.7355"
```

```
[1] "Based on Min BIC Val - Adjusted R-Square: 0.7347"
```

Here we can see that the adjusted R-square is decreased but only for a small amount which indicates that it might be a better model compared to original model(including all predicates) as this model is comparatively less complex

Lets Check the various Residuals plot

```
[78]: par(mfcol=c(2,2))
plot(fit.reg.b.bic)
```

Analysis on the four plots

The **residual vs fitted plot**: This plot is used to check the linear assumption. It shows if residuals have non-linear patterns. If you find equally spread residuals around a horizontal line without distinct patterns, that is a good indication you have linear relationships. However, if the relationship between predictors and an response variable is non-linear, an obvious pattern could show up in this plot if the model cannot capture the non-linearity. The first plot above shows that there could be a non-linear relationship between critical_temp and all the predictors, as the residuals are not scattered evenly.

The **normal Q-Q plot**: The Q-Q plot (i.e., quantile-quantile plot) is a graphical tool to help us assess if a set of data plausibly came from some theoretical distribution such as a Normal. For example, if we run a statistical analysis that assumes our dependent variable is Normally distributed, we can use a Normal Q-Q plot to check that assumption. In the case of linear regression analysis, we assume that residual is normally distributed with constant variance and mean equal to zero. The normal Q-Q plot shows if residuals are normally distributed. Generally It is good if

residuals are lined well on the straight dashed line. In the above Plot it seems that the residuals are approximately distributed normally

The **scale-location plot**: It is used to check the assumption of equal variance by showing if residuals are spread equally along the ranges of predictors. It is good if we can see a horizontal line with equally (randomly) spread points. The scale-location plot shows that the residuals appear randomly spread.

The **residual-leverage plot**: it helps us identify influential data samples. Not all outliers are influential in linear regression analysis. Here we care about the samples that are influential to determine the regression line. These samples can be very influential even if they look to be within a reasonable range of the values. They can alter the results if we exclude them from analysis. In the residual-leverage plot, we look for outlying values at the upper right corner or at the lower right corner. Samples located in those places can be influential against a regression line. We usually use Cook's distance, indicated by a red dash line. When samples are outside of the Cook's distance (i.e, they have high Cook's distance scores, Cook's distance measures how much the entire regression function changes when the i-th case is deleted.), the samples are influential to the regression results. The regression results will be altered if we exclude those samples. Here in this plot we can barely see Cook's distance lines because all cases are well inside of the Cook's distance lines. Therefore no influential cases are observed.

4.1.14 Perform F-tests by comparing the two models using the `anova()` function

```
[79]: anova(fit.all, fit.reg.b.bic)
```

Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
14802	4594899	NA	NA	NA	NA
14823	4614922	-21	-20023.8	3.07165	2.690422e-06

Here with respect to the original Fit (including all predictors) we can see that in the new model the predictors are more correlated as p value is less than 0.05. we can also see that in the new fit the no of predictors is less compared to the original which makes it less complex. Also we can see that there is only slight increase in RSS compared to the original fit. So due to all these factors the new model looks better than the all predictors model

based on Adjusted R Square

So lets start from analysing the best model based on Adjusted R Square ie 76 predictors

```
[80]: bAdjRSelectedColumns = names(coef(fit.reg.backward,76))
# Chang in the value of '(Intercept) to critical_temp
bAdjRSelectedColumns[1] = 'critical_temp'

```

Residual standard error: 17.62 on 14807 degrees of freedom
Multiple R-squared: 0.7369, Adjusted R-squared: 0.7356
F-statistic: 545.7 on 76 and 14807 DF, p-value: < 2.2e-16

```

[83]: # -1 to remove the row with value as intercept
print(paste("we can see that in this model around", nrow(fit.reg.b.adj.r.
→summary$coefficients)-1,"predictors is been used"))

```

```
[1] "we can see that in this model around 76 predictors is been used"
```

```

[84]: print(paste("All Predictors - Adjusted R-Square:",round(fit.all.summary$adj.r.
→squared,4)))
print(paste("Backward Subset Selection Max Adjusted R Square Val - Adjusted_
→R-Square:",round(fit.reg.b.adj.r.summary$adj.r.squared,4)))

```

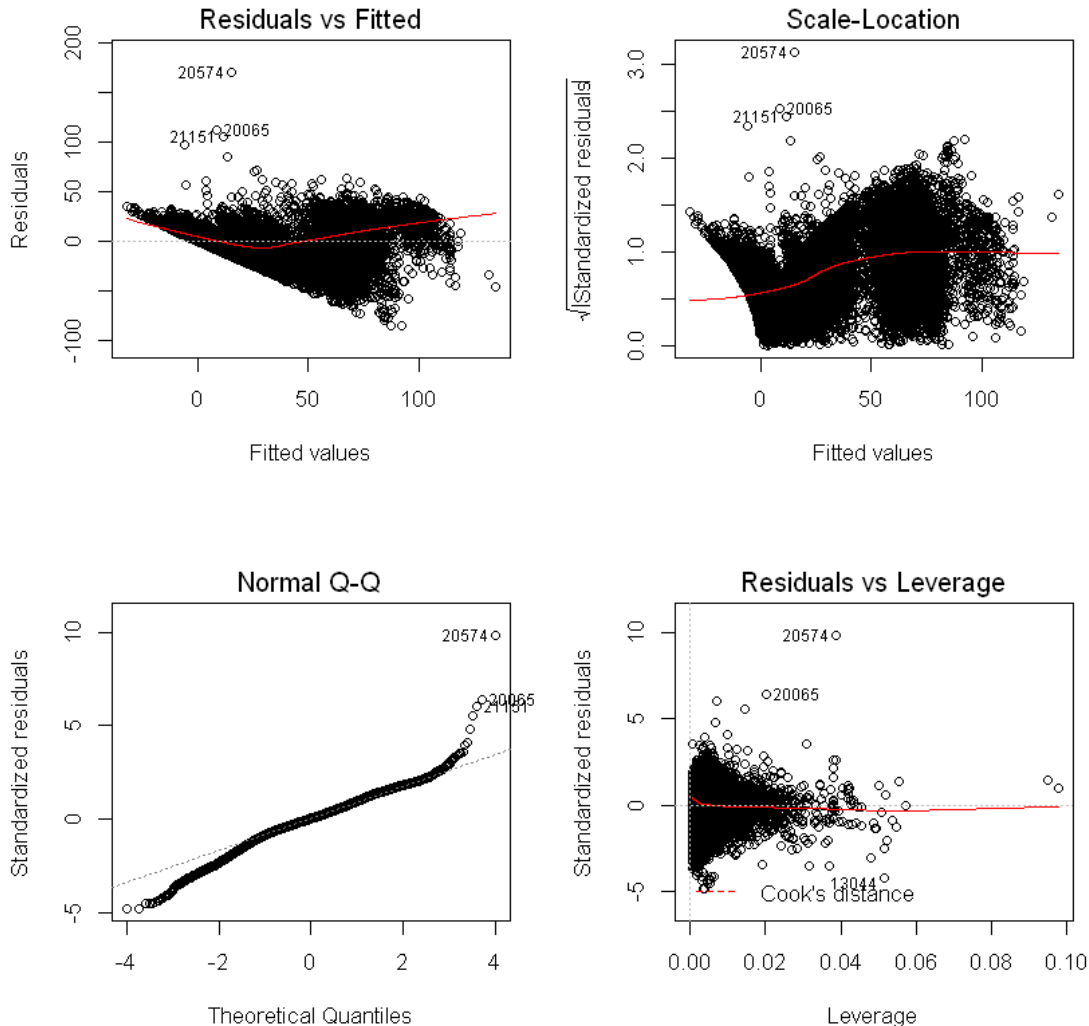

```
[1] "All Predictors - Adjusted R-Square: 0.7355"
```

```
[1] "Backward Subset Selection Max Adjusted R Square Val - Adjusted R-Square:
0.7356"
```

Here we can see that the adjusted R-square is increased which indicates that it might be a better model compared to original model(including all predicates) as this model is comparatively less complex

Lets Check the various Residuals plot

```
[85]: par(mfcol=c(2,2))
      plot(fit.reg.b.adj)
```

Analysis on the four plots

The **residual vs fitted plot**: This plot is used to check the linear assumption. It shows if residuals have non-linear patterns. If you find equally spread residuals around a horizontal line without distinct patterns, that is a good indication you have linear relationships. However, if the relationship between predictors and an response variable is non-linear, an obvious pattern could show up in this plot if the model cannot capture the non-linearity. The first plot above shows that there could be a non-linear relationship between critical_temp and all the predictors, as the residuals are not scattered evenly.

The normal **Q-Q plot**: The Q-Q plot (i.e., quantile-quantile plot) is a graphical tool to help us assess if a set of data plausibly came from some theoretical distribution such as a Normal. For

example, if we run a statistical analysis that assumes our dependent variable is Normally distributed, we can use a Normal Q-Q plot to check that assumption. In the case of linear regression analysis, we assume that residual is normally distributed with constant variance and mean equal to zero. The normal Q-Q plot shows if residuals are normally distributed. Generally It is good if residuals are lined well on the straight dashed line. In the above Plot it seems that the residuals are approximatly distributed normally

The **scale-location plot**: It is used to check the assumption of equal variance by showing if residuals are spread equally along the ranges of predictors. It is good if we can see a horizontal line with equally (randomly) spread points. The scale-location plot shows that the residuals appear randomly spread.

The **residual-leverage plot**: it helps us identify influential data samples. Not all outliers are influential in linear regression analysis. Here we care about the samples that are influential to determine the regression line. These samples can very influential even if they look to be within a reasonable range of the values. They can alter the results if we exclude them from analysis. In the residual-leverage plot, we look for outlying values at the upper right corner or at the lower right corner. Samples located in those places can be influential against a regression line. We usually use Cook's distance, indicated by a red dash line. When samples are outside of the Cook's distance (i.e, they have high Cook's distance scores, Cook's distance measures how much the entire regression function changes when the i-th case is deleted.), the samples are influential to the regression results. The regression results will be altered if we exclude those samples. Here in this plot we can barely see Cook's distance lines because all cases are well inside of the Cook's distance lines. Therefore no influential cases are observed.

4.1.15 Perform F-tests by comparing the two models using the `anova()` function

```
[86]: anova(fit.all, fit.reg.b.adjR)
```

Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
14802	4594899	NA	NA	NA	NA
14807	4595301	-5	-402.2139	0.2591383	0.9353668

Here with respect to the original Fit (including all predictors) we can see that in the new model the predictors are not much correlated as p value is greater than 0.05. we can also see that in the new fit the no of predictors is less compared to the original which makes it less complex. Also we can see that there is only slight increase in RSS compared to the original fit. So due to all these factors the new model looks better than the all predictors model

based on Cp

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 17.62 on 14813 degrees of freedom

Multiple R-squared: 0.7367, Adjusted R-squared: 0.7355

F-statistic: 592.2 on 70 and 14813 DF, p-value: < 2.2e-16

```

[90]: # -1 to remove the row with value as intercept
print(paste("we can see that in this model around", nrow(fit.reg.b.cp.
  ↳summary$coefficients)-1,"predictors is been used"))

```

```
[1] "we can see that in this model around 70 predictors is been used"
```

```

[91]: print(paste("All Predictors - Adjusted R-Square:",round(fit.all.summary$adj.r.
  ↳squared,4)))
print(paste("Based on Min Cp Val - Adjusted R-Square:",round(fit.reg.b.cp.
  ↳summary$adj.r.squared,4)))

```

```
[1] "All Predictors - Adjusted R-Square: 0.7355"
```

```
[1] "Based on Min Cp Val - Adjusted R-Square: 0.7355"
```

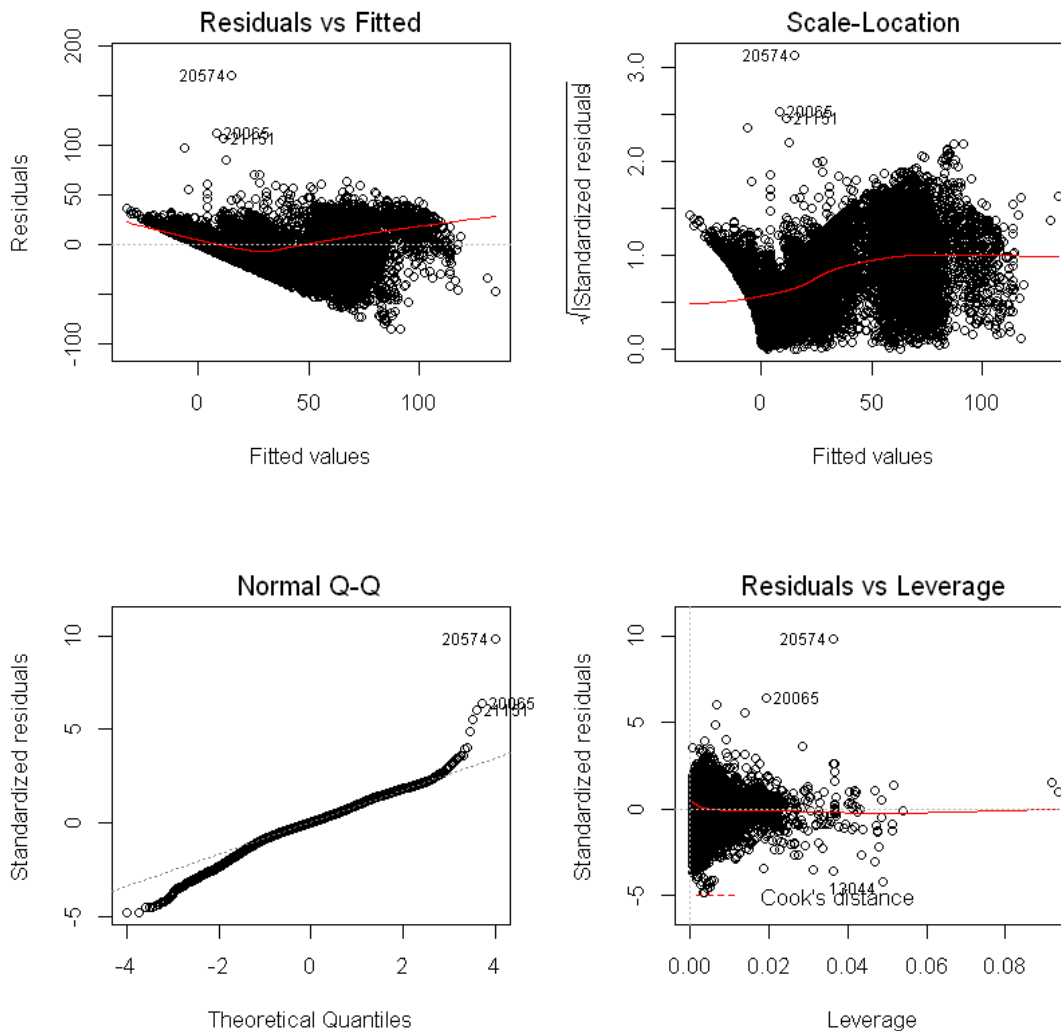

Here we can see that the adjusted R-square is decreased but only for a small amount which indicates that it might be a better model compared to original model(including all predicates) as this model is comparatively less complex

Lets Check the various Residuals plot

```

[92]: par(mfcol=c(2,2))
plot(fit.reg.b.cp)

```

Analysis on the four plots

The **residual vs fitted plot**: This plot is used to check the linear assumption. It shows if residuals have non-linear patterns. If you find equally spread residuals around a horizontal line without distinct patterns, that is a good indication you have linear relationships. However, if the relationship between predictors and an response variable is non-linear, an obvious pattern could show up in this plot if the model cannot capture the non-linearity. The first plot above shows that there could be a non-linear relationship between critical_temp and all the predictors, as the residuals are not scattered evenly.

The **normal Q-Q plot**: The Q-Q plot (i.e., quantile-quantile plot) is a graphical tool to help us assess if a set of data plausibly came from some theoretical distribution such as a Normal. For example, if we run a statistical analysis that assumes our dependent variable is Normally distributed, we can use a Normal Q-Q plot to check that assumption. In the case of linear regression analysis, we assume that residual is normally distributed with constant variance and mean equal to zero. The normal Q-Q plot shows if residuals are normally distributed. Generally It is good if

residuals are lined well on the straight dashed line. In the above Plot it seems that the residuals are approximately distributed normally

The **scale-location plot**: It is used to check the assumption of equal variance by showing if residuals are spread equally along the ranges of predictors. It is good if we can see a horizontal line with equally (randomly) spread points. The scale-location plot shows that the residuals appear randomly spread.

The **residual-leverage plot**: it helps us identify influential data samples. Not all outliers are influential in linear regression analysis. Here we care about the samples that are influential to determine the regression line. These samples can be very influential even if they look to be within a reasonable range of the values. They can alter the results if we exclude them from analysis. In the residual-leverage plot, we look for outlying values at the upper right corner or at the lower right corner. Samples located in those places can be influential against a regression line. We usually use Cook's distance, indicated by a red dash line. When samples are outside of the Cook's distance (i.e, they have high Cook's distance scores, Cook's distance measures how much the entire regression function changes when the i-th case is deleted.), the samples are influential to the regression results. The regression results will be altered if we exclude those samples. Here in this plot we can barely see Cook's distance lines because all cases are well inside of the Cook's distance lines. Therefore no influential cases are observed.

4.1.16 Perform F-tests by comparing the two models using the `anova()` function

[93]: `anova(fit.all, fit.reg.b.cp)`

Res.Df	RSS	Df	Sum of Sq	F	Pr(>F)
14802	4594899	NA	NA	NA	NA
14813	4598388	-11	-3488.991	1.021766	0.4234977

Here with respect to the original Fit (including all predictors) we can see that in the new model the predictors are not much correlated as p value is greater than 0.05. we can also see that in the new fit the no of predictors is less compared to the original which makes it less complex. Also we can see that there is only slight increase in RSS compared to the original fit. So due to all these factors the new model looks better than the all predictors model

5 Model Accuracy Analysis

5.1 Mean Square Error

```
[94]: print(paste("allPredictorsFit --",mean((predict(fit.all, test, type="response") -
      ↪ test$critical_temp)^2)))
print(paste("highlyCorrelatedTrain --",mean((predict(fit.correlated, test,
      ↪ type="response") - test$critical_temp)^2)))
print(paste("Backward Subset Selection(Min BIC) --",mean((predict(fit.reg.b.
      ↪ bic, test, type="response") - test$critical_temp)^2)))
print(paste("Backward Subset Selection(Max Adjusted R Square)
      ↪ --",mean((predict(fit.reg.b.adjR, test, type="response") -
      ↪ test$critical_temp)^2)))
print(paste("Backward Subset Selection(Min Cp) --",mean((predict(fit.reg.b.cp,
      ↪ test, type="response") - test$critical_temp)^2)))
```

```
print(paste("Forward Subset Selection(Min BIC) --",mean((predict(fit.reg.f.bic,
→test, type="response") - test$critical_temp)^2)))
print(paste("allStarredFit --",mean((predict(fit.starred, test,
→type="response") - test$critical_temp)^2)))
print(paste("stepBackwardFit --",mean((predict(fit.step.backward, test,
→type="response") - test$critical_temp)^2)))
print(paste("stepForwardFit --",mean((predict(fit.step.forward, test,
→type="response") - test$critical_temp)^2)))
```

```
[1] "allPredictorsFit -- 308.659073948539"
[1] "highlyCorrelatedTrain -- 407.498966463707"
[1] "Backward Subset Selection(Min BIC) -- 310.038796898743"
[1] "Backward Subset Selection(Max Adjusted R Square) -- 308.692559505932"
[1] "Backward Subset Selection(Min Cp) -- 308.808740104244"
[1] "Forward Subset Selection(Min BIC) -- 308.72306329421"
[1] "allStarredFit -- 309.09531579758"
[1] "stepBackwardFit -- 308.808740104244"
[1] "stepForwardFit -- 308.522895393448"
```

Here except for the highlyCorrelatedTrain all other models have almost same mean square error. So for rest of the models we can also compare its adjusted R square value and also no of predictors used to determine which is the best model.

5.2 Adjusted R Square of Different Models

```
[95]: print(paste("allPredictorsFit --",round(fit.all.summary$adj.r.squared,4)))
print(paste("Backward Subset Selection(Min BIC) --",round(fit.reg.b.bic.
→summary$adj.r.squared,4)))
print(paste("Backward Subset Selection(Max Adjusted R Square) --",round(fit.reg.
→b.adj.r.summary$adj.r.squared,4)))
print(paste("Backward Subset Selection(Min Cp) --",round(fit.reg.b.cp.
→summary$adj.r.squared,4)))
print(paste("Forward Subset Selection(Min BIC) --",round(fit.reg.f.bic.
→summary$adj.r.squared,4)))
print(paste("allStarredFit --",round(fit.starred.summary$adj.r.squared,4)))
print(paste("stepBackwardFit --",round(fit.step.backward.summary$adj.r.
→squared,4)))
print(paste("stepForwardFit --",round(fit.step.forward.summary$adj.r.
→squared,4)))
```

```
[1] "allPredictorsFit -- 0.7355"
[1] "Backward Subset Selection(Min BIC) -- 0.7347"
[1] "Backward Subset Selection(Max Adjusted R Square) -- 0.7356"
[1] "Backward Subset Selection(Min Cp) -- 0.7355"
[1] "Forward Subset Selection(Min BIC) -- 0.7352"
[1] "allStarredFit -- 0.7353"
```

```
[1] "stepBackwardFit -- 0.7355"
[1] "stepForwardFit -- 0.7354"
```

Here we can see that the adjusted R square values are also approximately same for all the models. So let's make a decision based on the no of predictors

5.3 No of Predictors Used

```
[96]: print(paste("allPredictorsFit --", nrow(fit.all.summary$coefficients)-1))
print(paste("Backward Subset Selection(Min BIC) --", nrow(fit.reg.b.bic.
  ↳summary$coefficients)-1))
print(paste("Backward Subset Selection(Max Adjusted R Square) --", nrow(fit.reg.
  ↳b.adj.r.summary$coefficients)-1))
print(paste("Backward Subset Selection(Min Cp) --", nrow(fit.reg.b.cp.
  ↳summary$coefficients)-1))
print(paste("Forward Subset Selection(Min BIC) --", nrow(fit.reg.f.bic.
  ↳summary$coefficients)-1))
print(paste("allStarredFit --", nrow(fit.starred.summary$coefficients)-1))
print(paste("stepBackwardFit --", nrow(fit.step.backward.
  ↳summary$coefficients)-1))
print(paste("stepForwardFit --", nrow(fit.step.forward.summary$coefficients)-1))
```

```
[1] "allPredictorsFit -- 81"
[1] "Backward Subset Selection(Min BIC) -- 60"
[1] "Backward Subset Selection(Max Adjusted R Square) -- 76"
[1] "Backward Subset Selection(Min Cp) -- 70"
[1] "Forward Subset Selection(Min BIC) -- 73"
[1] "allStarredFit -- 67"
[1] "stepBackwardFit -- 70"
[1] "stepForwardFit -- 77"
```

Here we can see that the Model that we selected using backward subset selection and which had the min BIC value can be considered as the best model out of these models as it is more simple model compared to rest of the models. As it is able to almost predict the values with just 60 predictors

Summary of the model that we have selected is shown below

```
[97]: fit.reg.b.bic.summary
```

Call:

```
lm(formula = critical_temp ~ ., data = bBicTrain)
```

Residuals:

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 17.64 on 14823 degrees of freedom

Multiple R-squared: 0.7358, Adjusted R-squared: 0.7347

F-statistic: 688 on 60 and 14823 DF, p-value: < 2.2e-16

Based on This The subset of Attributes That act as most significant are:

[110]: `coef(fit.reg.b.bic.summary)`
